Pharmacodynamics:
(Principles & Basic Mechanisms of Drug Action)

VPT: Unit I; Lecture-19
(Dated 26.11.2020)

Dr. Nirbhay Kumar
Asstt. Professor & Head
Deptt. of Veterinary Pharmacology & Toxicology
Bihar Veterinary College, Bihar Animal Sciences University, Patna
Pharmacodynamics

- It is the study of physiological and biochemical effects of drugs and how these effects relate to a drug's mechanism of action.

- This aspect of Pharmacology deals with action of drugs within the body and, therefore, is concerned mainly with the interaction of drugs with their target sites.

- Correlation between pharmacological activity and chemical structure of the drug.
Pharmacodynamics

- Paul Ehrlich saying:

  "Corpora non agunt nisi fixata",

  which means 'A drug will not work unless it is bound'.

- These critical binding sites are often referred to as 'DRUG TARGETS'.

contd...
Principles of Drug Action
Principles of Drug Action

- Drugs (except those gene based) **do not impart new functions** to any system, organ or cell.

- They only **alter the pace** of ongoing activity.

- Basic types of drug action :-
  (i) Stimulation
  (ii) Depression
  (iii) Irritation
  (iv) Replacement
  (v) Cytotoxic action
1. STIMULATION

- It is a *selective enhancement* of the level of activity of specialized cells.

- Example - adrenaline stimulates heart, pilocarpine stimulates salivary glands.

- However, excessive stimulation is often followed by depression of that function. Example - High dose of picrotoxin, a CNS stimulant produces convulsions followed by coma and respiratory depression.
2. DEPRESSION

- It is a **selective diminution** of activity of specialized cells.
- Example - Barbiturates depress CNS, quinidine depresses heart.
- Certain drugs stimulate one type of cells but depress the other. Example - acetylcholine stimulates intestinal smooth muscles but depress the SA node in the heart.
- Most drugs **can not be just classed as stimulants or depressants**.
3. IRRITATION

- A non-selective, often noxious effect and is particularly applied to specialized cells like epithelium, connective tissue etc.

- Mild irritation may stimulate associated function like bitters increase salivary and gastric secretions and counterirritants increase blood flow to the site.

- But strong irritation results in inflammation, corrosion, necrosis and morphological damage. This may result in diminution or loss of function.
4. REPLACEMENT

• This refers to the use of natural metabolites, hormones or their congeners in deficiency states like insulin in diabetes and fluids in dehydration.

5. CYTOTOXIC ACTION

• Selective cytotoxic action for invading parasites or cancer cells, attenuating them without significantly affecting the host cells is utilized for cure or palliation of infections and neoplasms.
Basic Mechanisms of Drug Action
[I]. NON-CELLULAR MECHANISMS OF DRUG ACTION

1. Physical effects
   - Examples include protective, adsorbent and lubricant properties of locally active agents that are applied to cutaneous and membrane surfaces.

2. Chemical reactions
   - A number of drugs produce their effects through a chemical union with an endogenous or foreign substance.
3. Physicochemical mechanisms

- Certain drugs act by altering the physicochemical or biophysical properties of specific fluids or even components of cells.
- Examples of the former include the surface-active agents or surfactants.
- Detergents, emulsifiers, antifoaming agents and several antiseptics and disinfectants possess surfactant properties.
4. Modifications of the composition of body fluids:

- Several therapeutic manipulations involve the administration of substances that exert osmotic effects across particular cell membranes.

- Examples of osmotically active agents include magnesium sulphate as a purgative, mannitol as a diuretic, hypertonic poultices applied to the skin and use of dextran as plasma volume expander.
1. Physicochemical and biophysical mechanisms

- Certain drugs appear to act by altering the physicochemical or biophysical characteristics of specific components of cells.

- Examples include the effect of general inhalant anaesthetics on the lipid matrix and perhaps the hydrophobic proteins in neuronal membranes within the CNS.
Cellular mechanisms of drug action  contd...

2. Modification of cell membrane structure and function

• Various drugs may influence either the structure or specific functional components of cell membranes and thereby initiate their characteristic effects. These mechanisms of action may also involve enzyme systems or receptor mediated reactions.

• A few examples include, local anaesthetics that bind to components of the sodium channels in excitable membranes and prevent depolarization, calcium channel blockers that inhibit the entry of calcium into cells.
3. Mechanisms associated with neurohumoural transmission

- A number of drugs interfere with the synthesis, release, effects or re-uptake of neurotransmitters. Once again enzyme and/or receptor mediated effects may be responsible.

- For example, reserpine blocks the transport system of adrenergic storage granules, while amphetamine displaces norepinephrine from axonal terminals. Botulinum toxin prevents the release of acetylcholine from cholinergic terminals and bretylium inhibits the release of norepinephrine from adrenergic terminals.
4. Enzyme Inhibition

• Certain enzymes exert their effects by inhibiting the activity of specific enzyme systems either in the host animal or the invading pathogens. This inhibition may be competitive or non-competitive. Non-competitive inhibition may be reversible or irreversible.
Thank You
